

The planet Nibiru filmed near our Sun?

On March 22, 2022, ufologist Scott C. Waring published an article on his blog claiming the presence of a **dark, spherical object** near the Sun in images captured by NASA's Solar Dynamics Observatory (SDO) on March 10th and 14th, 2022.

According to Waring, the object, spotted by Twitter user Bruce Fenton, is visible for only a few minutes in the SDO's LASCO C2 telescope photos. He claims it's a solid sphere spotted in two different locations near the Sun over a four-day period. Waring speculates it could be the mysterious Planet Nibiru (also called Planet X), fueling his theory with the idea that only an advanced alien spacecraft could be hidden so effectively from humanity.

However, more rational explanations exist. The SDO's images capture the Sun in various wavelengths, and artifacts caused by image processing or natural solar phenomena can sometimes appear as unidentified objects.
